45. The read access times and the hit ratios for different caches in a memory hierarchy are as given below.

| Cache | Read access time <br> (in nanoseconds) | Hit ratio |
| :---: | :---: | :---: |
| I-cache | 2 | 0.8 |
| D-cache | 2 | 0.9 |
| L2-cache | 8 | 0.9 |

The read access time of main memory is 90 nanoseconds. Assume that the caches use the referred wordfirst read policy and the write back policy. Assume that all the caches are direct mapped caches. Assume that the dirty bit is always 0 for all the blocks in the caches. In execution of a program, $60 \%$ of memory reads are for instruction fetch and $40 \%$ are for memory operand fetch. The average read access time in nanoseconds (up to 2 decimal places) is $\qquad$ _.
